Similarity as basis for probability judgements

► Skip slide

In his classic 1937 article, de Finetti wondered:

“How should an insurance company evaluate the probability that an individual dies in a given year?”

De Finetti's view was:

- First choose a class of “similar” events
- use the frequency as base-line estimate of the probability
 - e.g., : “death in a given year of an individual of the same age [...] and living in the same country.”
- The choice of a class of “similar” events is subjective
 - ..maybe “not individuals of the same age and country, but those of the same profession and town, . . . etc, where one can find a sense of ‘similarity’ that is also plausible.”

Three fundamental ideas

► Skip slide

1 *Similarity is not optional:*

probability judgements are founded on similarity

2 *Similarity is exchangeability*

exchangeability *formalizes* the notion of similarity

3 *Similarity is subjective*

Similarity is the decision maker's *model* or *theory* of the world.

“we cannot repeat an experiment and look for a covering theory; we must have at least a partial theory before we know whether we have a repetition of the experiment.”

Alternative title:
Similarity First!

De Finetti's ideas in action

► Skip slide

- Sequence of experiments, each with outcome \mathcal{S}
 - \mathcal{S} is Polish (complete, separable metric space)
 - σ -algebra \mathcal{S}

- State space:

$$\Omega = \mathcal{S} \times \mathcal{S} \times \dots$$

- Generic element $\omega = (s_1, s_2, \dots)$
 - Borel σ -algebra Σ on Ω
- Decision problem is static, but an inter-temporal interpretation may be suggestive.

Acts and permutations

► Skip slide

- An act is any bounded, measurable function

$$f : \Omega \rightarrow \mathbb{R}$$

- Interpret values of acts as utils
 - \mathcal{F} set of all acts
-
- Π is the set of finite permutations π
 - Given an act f and a permutation π , define $f \circ \pi$ by

$$f \circ \pi(\mathbf{s}_1, \mathbf{s}_2, \dots) = f(\mathbf{s}_{\pi(1)}, \mathbf{s}_{\pi(2)}, \dots)$$

Stylized example: *coin tosses*

► Skip slide

- $S = \{H, T\}$; generic $\omega = \{H, T, T, H, \dots\}$
- You might be interested in betting on the i th coin turning *Heads*
- Typical assumption:
“the experiment is repeated under identical conditions”
- *“Absurd!”* says de Finetti !!
- If the experiments were really identical, then the coin should either always turns up H or always T

Exchangeability as model of similarity

► Skip slide

- The fact that the outcome varies means that there are important factors that I do not understand or care to model
- But I *judge* the experiments as “similar”
- ..means: these factors affect experiments symmetrically

De Finetti's exchangeability: for all $f \in \mathcal{F}, \pi \in \Pi$

$$f \sim f \circ \pi.$$

In the stylized coin example, H is equally likely in all experiments

$$\text{Heads in toss } i \sim \text{Heads in toss } j$$

De Finetti's Theorem

► Skip slide

De Finetti's theorem: a preference that is

- 1 exchangeable *and*
- 2 subjective expected utility

.. has the representation

$$P(A) = \int_{\theta \in \Theta} P^\theta(A) d\mu.$$

- 1 **Parameters:** i.i.d. distributions P^θ indexed by $\theta \in \Theta \equiv \Delta(S)$
- 2 **Bayesian belief** μ over the parameters Θ

De Finetti's Theorem and its discontents

► Skip slide

Contentment: Parameters formally capture the extent to which experiments are similar

- experiments are different enough to have different outcomes, but similar enough to share a common distribution P^θ

The discontents: de Finetti's theorem confounds similarity with the decision criterion. It simultaneously identifies

- the parameters Θ
- and that the decision maker has a prior about them:

$$P(A) = \int_{\theta \in \Theta} P^\theta(A) d\mu.$$

..but how about classical statisticians, ambiguity, etc?

Similarity is an overarching principle for all decision making and inference; Bayesianism is not.

- 1 Introduction
- 2 Structure

- 4 Sufficient statistics
- 5 Ergodicity
- 6 Ambiguity
- 7 Conclusions
- 8 Appendix

Preorder and Monotonicity

► Skip slide

Assumption 1: \succsim is reflexive and transitive.

(may be incomplete)

Assumption 2: If $f(\omega) \geq g(\omega)$ for all $\omega \in \Omega$, then $f \succsim g$.

Assumption 3: For every $x, y \in \mathbb{R}$,

$$x > y \implies x \succ y.$$

Old Assumption: For any $\alpha \in \mathbb{R}$, $f \succsim g$ implies

$$f + \alpha \succsim g + \alpha.$$

Null sets

► Skip slide

An event E is \succsim -null if any pair of acts that differ only on E are indifferent.

Assumption 4:

- $1_E \sim 0 \implies E$ is null;
- $\alpha 1_E \succsim \beta 1_E$ for some $\beta > \alpha \implies E$ is null.

Continuity

► Skip slide

We require continuity with respect to:

$$f^n \rightarrow f \iff \left\{ \omega \in \Omega : \lim_n f^n(\omega) \neq f(\omega) \right\} \approx \text{is-null}$$

Assumption 5:

- $f^n \rightarrow f$ and $g^n \rightarrow g$;
- $f^n \approx g^n$ for all n
- $|f^n(\omega)| \leq b(\omega)$ and $|g^n(\omega)| \leq b(\omega)$, for all ω and some $b \in \mathcal{F}$.

Then $f \approx g$.

Exchangeability

► Skip slide

De Finetti's condition:

$$f \sim f \circ \pi$$

has little force without expected utility. In our more general setting, we need a stronger condition.

Definition

A preference \succsim is *exchangeable* if for every act $f \in \mathcal{F}$ and permutations π_1, \dots, π_n

$$f \sim \frac{f \circ \pi_1 + \dots + f \circ \pi_n}{n}.$$

Stylized coin example:

Heads in toss $i \sim$ average of *Heads* in tosses $1, \dots, n$

To simplify the exposition, for the remainder of the paper:

restrict to the set of acts \mathcal{F}_1 that
depend only on the first
coordinate

Shifting states

► Skip slide

$s_1 \setminus$

Shifting acts

► Skip slide

Subjective Ergodic Theorem

If \succsim is exchangeable then for every act f , the act

$$f^*(\omega) \equiv \lim_{n \rightarrow \infty} \frac{1}{n} \sum_{j=0}^{n-1} f(T^j \omega)$$

- is well-defined, except on a \succsim -null event, and
- $f^* \sim f$.

Note that f^* , when it exists, is objective. Its existence is consequence of subjective assessment of similarity

Ergodic Decomposition

► Skip slide

$$E^{\theta(\omega)} \equiv (f^*)^{-1}(\omega) \equiv \{ \text{all states } \omega' \text{ such that } f^*(\omega') = f^*(\omega) \}$$

Ergodic Decomposition

► Skip slide

Starting from ω , T defines an orbit that remains in $E^{\theta(\omega)}$

Subjective Ergodic Decomposition

There is a parametrization $\{(E^\theta, P^\theta)\}_{\theta \in \Theta}$ such that:

- the E^θ 's partition Ω
- P^θ is the unique exchangeable distribution supported by E^θ :

$$P^\theta(E^\theta) = 1$$

For every exchangeable preference \succsim and parameter θ

- For P^θ -almost all $\omega \in E^\theta$:

$$f^*(\omega) = \int_{\Omega} f dP^{\theta(\omega)}.$$

Ergodic Decomposition

► Skip slide

Starting with ω , we obtain same answer if we:

- compute the ‘objective’ frequentist limit: $f^*(\omega)$
- calculate the expected utility: $\int_{\Omega} f dP^{\theta(\omega)}$

Quick note on 'learning'

► Skip slide

- Infinite data $\implies \omega$ is observed $\implies \theta$ can be learned
- But the model does not admit a mechanism to change the exchangeability relationship
- $\{(E^\theta, P^\theta)\}$ is the decision maker's window to the world!
His way to organize information.
- The decision maker interprets the sequence

H, T, H, T, H, \dots

as confirming that $\theta = 0.5$

Sufficient statistics: *Goal and summary*

► *Skip slide*

We will show that the i.i.d. parametrization Θ is sufficient, in the sense of sufficient statistics, for the class of exchangeable preferences.

Sufficient statistics

► Skip slide

- In statistics, a parameter is sufficient for a family of distributions if it contains all “relevant information” about that family
- Formally, a σ -algebra \mathcal{Z} is sufficient for a family of distributions \mathcal{P} if

$$P(\cdot | \mathcal{Z})$$

does not depend on $P \in \mathcal{P}$.

- Here we have preferences, not distributions, so this cannot make sense for us

Subjective Sufficient Statistics

► Skip slide

- Define $\mathcal{F}_\Theta \subset \mathcal{F}$ to be the set of acts measurable with respect to $\{E^\theta\}_{\theta \in \Theta}$.
- Define the mapping

$$\Phi : \mathcal{F} \rightarrow \mathcal{F}_\Theta \quad \text{by} \quad \Phi(f)(\omega) = \int_{\Omega} f dP^{\theta(\omega)}.$$

- We allow ambiguity *about* parameters, of course.
- However, a parameter *means* that, once its value is known, acts are evaluated using expected utility.

Subjective Sufficient Statistic Theorem

The i.i.d. parametrization Θ is *sufficient* for the set of exchangeable preferences:

For every f and g

$$f \succcurlyeq g \iff \Phi(f) \succcurlyeq \Phi(g).$$

- The **parameter-based act** associated with f :

$$F(\theta) \equiv \Phi(f)(\theta) \equiv \int_{\Omega} f dP^{\theta}.$$

- \succcurlyeq induces a preference \succcurlyeq on parameter-based acts:

$$f \succcurlyeq g \iff F \succcurlyeq G.$$

The Classic de Finetti's Theorem

An expected utility preference \succsim is exchangeable if and only if there is a belief μ on Θ such that:

$$F \succsim G \iff \int_{\Theta} F d\mu \geq \int_{\Theta} G d\mu.$$

This confounds:

- similarity-based, statistical constructs:

$P^{\theta'}_s$

- Bayesian criterion to resolve uncertainty about parameters

μ

with no statistical or similarity interpretation

Inter-subjective consensus

► *Skip slide*

Corollary

Let \succsim be any exchangeable preference.

If all exchangeable Bayesians prefer f to g , then so would \succsim .

Ergodicity: *Goals*

► *Skip slide*

We introduce learning-style conditions that imply subjective expected utility.

Ergodicity

► Skip slide

*Shift by
 i places*

Subjective Probabilities as Frequencies

► Skip slide

- E is *invariant* if $T(E) = E$;
- \succsim is *ergodic* if
 - 1 it is exchangeable, and
 - 2 E is invariant \implies either E or E^c is \succsim -null.

Empirical distributions

► Skip slide

- The *empirical distribution* at ω is the set-function which assigns to each event A the value

$$\nu(A, \omega) \equiv 1_A^*(\omega),$$

if this value exists, and is not defined otherwise.

- this is just the empirical frequency of A along ω .

Subjective Probability from Frequencies

If \succsim is ergodic, then:

- There is an event Ω' with \succsim -null complement, such that the empirical distribution $\nu(\cdot) = \nu(\cdot, \omega)$ is a well-defined probability distribution on \mathcal{S} that is constant in $\omega \in \Omega'$; and
- \succsim restricted to \mathcal{F}_1 is an expected utility preference with subjective probability ν .

Different derivations

► Skip slide

Savage's theory:

normative axioms: P1, P2, P4, P6

+

exchangeability

⇓

exchangeable subjective probability P

Our result:

Exchangeability & Ergodicity

⇓

Expected utility: subjective belief = empirical measure ν

thus, P1, P2, P4, P6 !!

Statistical ambiguity: *Goal*

► *Skip slide*

We define and characterize unambiguous events purely based on learning foundations.

Statistical ambiguity: *Summary*

► *Skip slide*

Assume our weak assumptions

Exchangeability

(but no substantive ambiguity-flavor assumptions: eg incompleteness, ambiguity aversion..)

- (a) Subjective set of priors driven by learning conditions
- (b) expected utility on statistically unambiguous events
- (c) no implications about the attitude towards ambiguity
(no pessimism, fear of malevolent nature..)

Statistical ambiguity

► *Skip slide*

Assume:

- finite outcome space S
- focus on the set of acts \mathcal{F}_1 that depend only on the first coordinate.

Definition

Given a family of subsets $\mathcal{C} \subset 2^S$, a partial probability ν on \mathcal{C} is a function $\nu : \mathcal{C} \rightarrow [0, 1]$ such that there is a probability distribution on S that agrees with ν on \mathcal{C} .

Statistical ambiguity

► Skip slide

Definition

An event $A \subset S$ is \succsim -*statistically unambiguous* if there is $\Omega' \in \Sigma$ with \succsim -null complement, such that the frequency of A , $\nu(A) = \nu(A, \omega)$, is constant in $\omega \in \Omega'$.

The crucial part of the definition is the requirement that $\nu(A, \omega)$ is independent of ω off a \succsim -null set.

Characterization

► Skip slide

Theorem (Statistical Ambiguity)

Assume S is finite. For any exchangeable preference \succsim

- *The set of \succsim -statistically unambiguous events $\mathcal{C} \subset 2^S$ is a λ -system, i.e., a family of sets closed under complements and disjoint unions;*
- *The empirical measure $\nu(\cdot)$ is a partial probability on \mathcal{C} ; and*
- *For every \mathcal{C} -measurable acts $f, g \in \mathcal{F}_1$:*

$$f \succsim g \iff \int f d\nu \geq \int g d\nu.$$

\mathcal{C} is only a λ -system.

Concluding remarks

► Skip slide

- De Finetti understood the distinction between
 - ① *Defining* subjective probability, and
 - ② *Formulating* probability judgements
- Current conception of subjective probability emphasizes the first, and largely ignores the second
- Exchangeability, as formal model of similarity, is the part of the preference on which probability judgements are based
- This paper does what de Finetti's theorem cannot do:
separate similarity judgements from the decision criterion

Moving forward

► *Skip slide*

- An exchangeability relationship is the decision maker's *theory*, of what constitutes similar experiments
- ..but so far we have nothing to say about theory choice, theory change...
- Given our results, we can potentially talk about
 - Normative criteria that guide theory or model choice
 - Model uncertainty
 - Integrating classical and Bayesian methods

The End!!

► *Skip slide*

Epstein-Seo, Part 1

► Skip slide

Epstein-Seo. Part 1, strengthen:

$$f \sim f \circ \pi$$

to:

$$\alpha f + (1 - \alpha) f \circ \pi \sim f \quad (*)$$

Under our general assumptions, our condition

$$f \sim \frac{f \circ \pi_1 + \dots + f \circ \pi_n}{n}.$$

neither implies nor is it implied by (*)

More important is the difference between our results

Epstein-Seo, Part 1

► Skip slide

Assume our weak assumptions plus exchangeability

Epstein-Seo, Part 1:

Gilboa-Schmeidler axioms (completeness, C-indep., ambiguity aversion)

- (1) Gilboa-Schmeidler set of priors is exchangeable;
- (b) pessimistic MEU criterion given this set

Our approach:

Various learning conditions

- (a) Subjective set of priors driven by learning conditions;
- (b) no implications about the attitude towards statistical ambiguity

Epstein-Seo, Part 2

► Skip slide

Epstein-Seo second model maintains:

$$f \sim f \circ \pi$$

but allow:

$$\alpha f + (1 - \alpha)f \circ \pi \succ f \quad (*)$$

Now, parameters are *sets of measures*; the representation is a probability distribution over sets of measures

Examples of parameters:

- the set of all Dirac measures on Ω is a possible parameter
- so is the set of all independent distributions
- the set of all independent distributions with marginals belonging to $\{.2, .6\}$
- or to $\{.43, .91\}$, ... etc.

Epstein-Seo, Part 2

▶ *Skip slide*

- Important contribution because it shows the sort of anomalies that might arise when exchangeability is weakened.
- A parametrization where individual parameters are sets, including the set of all sample paths, seems far removed from the intuitive idea of parameters as useful devices to summarize information.
- It is difficult to imagine how statistical inference can proceed on this basis.
